Steady three dimensional gliding motion of an underwater glider

Shaowei Zhang, Jiancheng Yu, Aiqun Zhang, and Fumin Zhang

Abstract—Underwater Gliders have found broad applications in ocean sampling. In this paper, the nonlinear dynamic model of the glider developed by the Shenyang Institute of Automation, Chinese Academy of Sciences, is established. Based on this model, we solve for the parameters that characterize steady state spiraling motions of the glider. A set of nonlinear equations are simplified so that a recursive algorithm can be used to find the solutions.

I. INTRODUCTION

Gliders are autonomous controllable mobile platforms that use wing force and changing buoyancy as propulsion. Commercially available gliders include the Slocum [1], the Spray [2] and the Seaglider [3], which are capable of long range missions with low power consumption. Underwater gliders are employed in deep sea exploration [4] and ocean observation [5]–[7]. The dynamics of gliders are modeled in [8]–[11], and the straight line gliding motion in the vertical plane are stabilized by feedback control. The complex dynamic model and the coupled hydrodynamic effects make it difficult to find accurate solutions for the glider model that establishes relationships between the gliding state and the control input. The problem remains unsolved for three dimensional gliding motion such as the spiraling motion. In [9], a first attempt is made to find numerical solutions for the steady state equations that characterize the spiraling motion. In [12] and [13], an approximate analytical solution for steady spiraling motion is derived by applying perturbation theory.

The dynamic performance of an underwater glider is strongly affected by hydrodynamics. In [14], a thorough analysis about the hydrodynamic coefficients of a glider is performed. In [15], the drag and lift forces caused by wings of a fin-actuated underwater vehicle are studied. In [16], the hydrodynamic coefficients of autonomous underwater vehicles are verified using the computational fluid dynamics method and experiments. The effect of independently controllable wings on a glider is studied to enhance the glider maneuverability in [17].

The underwater glider developed by the Shenyang Institute of Automation (SIA) in [18] is propelled by a pump and a movable-rotatable battery mass. The hull with wings and tail attached is approximately cylindrical, and the control input. The problem remains unsolved for three dimensional gliding motion such as the spiraling motion. In [9], a first attempt is made to find numerical solutions for the steady state equations that characterize the spiraling motion. In [12] and [13], an approximate analytical solution for steady spiraling motion is derived by applying perturbation theory.

The pitch and roll are controlled by a movable-rotatable semi-cylindrical battery. A number of results are reported in the literature regarding the dynamics of gliders steered by rudders or by movable masses. However, less results exist for gliders steered by rotatable masses. A rotatable mass has effect on both the mass and the inertial distribution, with the hydrodynamics different from other types of gliders. We first derive the dynamic model for the SIA glider following the approaches established by [8]–[10]. Based on the model, we solve for the parameters that characterize steady state spiraling motion in 3D. Our goal is to characterize and control the spiraling motion, which is shared by [9] and [13]. We follow a different approach aiming to find the exact solutions. This approach requires us to significantly simplify the nonlinear equations resulting from the glider model. The simplified equations lead naturally to a recursive algorithm that requires less effort to compute than solving the original equations directly using numerical methods.

II. DYNAMICS OF THE SIA GLIDER

The SIA glider is modeled as a rigid body with fixed wing and tail. The control mechanisms include a buoyancy pump and a movable-rotatable battery mass. The hull with wings and tail attached is approximately cylindrical, and the center of buoyancy (CB) is designed to coincide with the geometric center of the cylinder. We assign the body coordinate frame as $e: (e_1, e_2, e_3)$ with its origin $e_o$ fixed at CB. Let $e_1$ lie along the longitudinal axis of the glider, and $e_2$ lie in the wing plane pointing to the right when viewed along the direction of $e_1$, $e_3$ is $e_1 \times e_2$, as shown in Fig.1. We denote the inertial frame as $E: (i, j, k)$ with its origin at $E_o$. The vector $b = [x \ y \ z]^T$ is the position of the glider from the origin of the inertial frame to the origin of the body frame and the posture referred by the Euler angles of the glider in the inertial frame is $\theta = [\phi \ \theta \ \psi]^T$. The glider moves through the fluid with the translational velocity $V = [V_1 \ V_2 \ V_3]^T$ and the angular velocity $\Omega = [\rho \ q \ r]^T$, all expressed with respect to the body frame. The rotation matrix $R_{EB}$ maps the velocity vector $V$ from the body frame to $v$ in the inertial frame as

$$v = \hat{v} = R_{EB}V$$ (1)

$$\dot{\theta} = \begin{bmatrix} 1 & s\phi\tan\theta & c\phi\tan\theta \\ 0 & c\phi & -s\phi \\ 0 & s\phi\sec\theta & c\phi\sec\theta \end{bmatrix} \Omega$$ (2)

where we use the notation $c=\cos(\cdot)$ and $s=\sin(\cdot)$, and
The different masses and position vectors are
respectively. The different masses and position vectors are
$m_{mr}$, $m_{mb}$, and $m_b$ in the body frame, respectively.

The stationary mass $m_{rb}$ includes the hull of the glider and
other rigid body mass, the movable mass $m_{mr}$ represents
the semi-cylindrical battery block, and the buoyancy mass is
$m_b$. The total mass of the glider can then be expressed as
follows

$$m_t = m_{rb} + m_{mr} + m_b$$

The mass of the displaced fluid is denoted as $m$. We define
$m_b = m_t - m$ so that the vehicle is negatively buoyant if
$m_b < 0$ and is positively buoyant if $m_b > 0$. $r_{rb}$, $r_{mr}$ and $r_b$ are the positions of $m_{rb}$, $m_{mr}$ and $m_b$ in the body frame,
respectively. The different masses and position vectors are
illustrated in Fig.1. We define the operator $\hat{\cdot}$ as the skew-
symmetric matrix constructed from a vector $\cdot$, for three-
dimensional column vectors $\mathbf{x}$ and $\mathbf{y}$, we have $\hat{\mathbf{xy}} = \mathbf{x} \times \mathbf{y}$.

A. Equations of Motion

We select $\mathbf{p}$ and $\mathbf{\pi}$ as the total translational momentum
and the angular momentum of the glider/fluid system in the
inertial frame. Let us assume that the translational velocity and
angular velocity of the battery are $\mathbf{V}_{mr} = 0$ and $\omega_{mr} = 0$. As in [8], according to the Newton’s laws, we know that,

$$\dot{\mathbf{p}} = \sum_{i=1}^{N} \mathbf{f}_{exti} + (m_{rb} + m_{mr} + m_b - m)g\mathbf{k}$$

$$\dot{\mathbf{\pi}} = \mathbf{q}_{mrE} \times m_{mr}g\mathbf{k} + \mathbf{q}_{be} \times m_b g\mathbf{k}$$

$$+ \mathbf{q}_{rbE} \times m_{rb}g\mathbf{k} + \sum_{j=1}^{N} \mathbf{f}_{extj}$$

where $\mathbf{k}$ is a unit vector pointing to the direction of gravity,
$\mathbf{f}_{exti}$ is the external force generated by the wing applied to
the system, and $\mathbf{f}_{extj}$ is a pure external moment. $\mathbf{f}_{intk}$ is the force applied from the vehicle to the point mass $m_{mr}$.

Vectors $\mathbf{q}_{mrE}$, $\mathbf{q}_{be}$, and $\mathbf{q}_{rbE}$ denote the position of the
centers of the battery mass, the buoyancy mass, and the rigid
body mass in the inertial frame, respectively.

We analyze the generalized velocity and the generalized
force of the glider in the body frame. First, we establish
the relationship between the velocity and momentum of the
glider in the body frame as

$$\eta = M\mathbf{v}$$

where $\mathbf{v} = [\mathbf{V} \ \Omega]$ are the translational velocity and
angular velocity of the glider system in the body frame; $\eta = [\mathbf{P}^T \ \Pi^T]^T$ are the generalized momentums of the
glider in the body frame, $\mathbf{P}$ and $\Pi$ are the translational
momentum and the angular momentum relative to the gilder body frame. $M$ is the generalized inertia matrix of the glider
system. By differentiating (6) with respect to time, we get
the relationship between the generalized force, velocity and
acceleration as

$$\ddot{\eta} = M\mathbf{v} + M\dot{\mathbf{v}}$$

Next, we derive the total kinetic energy of the glider system
to get $M$, $\mathbf{M}$, $\mathbf{\nu}$, and $\dot{\mathbf{v}}$.

As a stationary mass, the translational velocity and the
angular velocity of the rigid body $m_{rb}$ in the body frame
with respect to the origin $E_0$ can be expressed as

$$\mathbf{V}_{rbE} = \mathbf{V} + \Omega \times \mathbf{r}_{rb}$$

$$= \begin{bmatrix} 0 \\ I_3 \end{bmatrix} \mathbf{r}_{rb}$$

$$\Omega_{rbE} = \Omega$$

The kinetic energy of the rigid body mass is expressed as

$$T_{rb} = \frac{1}{2} \nu^T M_{rb} \nu$$

where

$$M_{rb} = \begin{bmatrix} m_{mr}I_3 & -m_{rb}\mathbf{r}_{rb} \\ m_{rb}\mathbf{r}_{rb}^T & I_{rb} - m_{rb}\mathbf{r}_{rb}\mathbf{r}_{rb}^T \end{bmatrix}$$

Similarly, the kinetic energy of the buoyancy mass $m_b$ is
derived as follows $T_b = \frac{1}{2} \nu^T M_b \nu$ where $I_b$ is the inertial
matrix of the buoyancy and

$$M_b = \begin{bmatrix} m_bI_3 & -m_b\mathbf{r}_b \\ m_b\mathbf{r}_b^T & I_b - m_b\mathbf{r}_b\mathbf{r}_b^T \end{bmatrix}$$

Accordingly, following [8], we express the kinetic energy
generated by the added mass $M_{fE}$, the added inertia matrix
$\mathbf{I}_{fE}$ and cross term $\mathbf{C}_{fE}$ due to the fluid effect as

$$T_f = \frac{1}{2} \nu^T M_f \nu$$

where

$$M_f = \begin{bmatrix} \mathbf{M}_{fE}^T \mathbf{C}_{fE} \mathbf{I}_{fE} \end{bmatrix}$$

We model the battery mass $m_{mr}$ as a semi-cylinder block.
The cross section of the glider’s battery is shown in Fig.2
with radius \(R_1\), length \(L\), and the eccentric distance \(R_{mr}\). In order to tune the roll and the pitch of the glider, the battery is controlled to move and rotate along the longitudinal axis \(e_1\). When the battery mass rotates around \(e_1\) with an angle \(\gamma\), the inertia matrix of the semi-cylinder block is a function of \(\gamma\) as

\[
I_{mr}(\gamma) = R_{e1}^T(\gamma)I_{mr}^0R_{e1}(\gamma)
\]

(11)

where

\[
R_{e1} = \begin{bmatrix}
1 & 0 & 0 \\
0 & \cos \gamma & -\sin \gamma \\
0 & \sin \gamma & \cos \gamma 
\end{bmatrix}
\]

and \(I_{mr}^0\) represents the principal inertia matrix of the semi-cylinder computed at the stationary state with \(\gamma = 0\). Since the semi-cylinder mass \(m_{mr}\) is constrained to move and rotate along the longitudinal axis \(e_1\), we denote vector \(r_{mr}e_1\) as the position in axis \(e_1\). Hence, the position \(r_{mr}\) and the angle velocity \(\Omega_{mr}\) in the body frame are expressed as

\[
r_{mr} = r_{mr}e_1 + R_{mr}(\cos(\gamma + \pi/2)e_2 + \sin(\gamma + \pi/2)e_3)
\]

(12)

\[
\Omega_{mr} = \dot{\gamma}e_1
\]

(13)

We differentiate \(r_{mr}\) to get the velocity \(V_{mr}\) of the semi-cylinder mass \(m_{mr}\) in the body frame as follows

\[
\dot{r}_{mr} = \dot{r}_{mr}e_1 + R_{mr}\dot{\gamma}(\cos \gamma e_2 - \sin \gamma e_3)
\]

\[
= V_{mr} - \mathbf{r}_{mr}\Omega_{mr}
\]

(14)

In order to get the kinetic energy of the battery mass, we derive the absolute velocity of the battery mass with respect to the origin of the inertial frame. The velocity of the battery block is defined as \(V_{mrE}\) in body frame with respect to the origin \(E_0\). The vector \(I_{mr}\) denotes the position of the point mass \(m_B\) in the inertial frame relative to the origin \(E_0\).

\[
r_{mr} = R_{EB}^TL_{mr} = R_{EB}^Tq_{mrE} - b
\]

(15)

Differentiating (15), we express the relationship between the velocity \(V_{mr}\) and the absolute velocity \(V_{mrE}\) as

\[
V_{mr} = R_{EB}^TL_{mr} + R_{EB}^Tq_{mrE} - b
\]

\[
= \dot{r}_{mr}\Omega + V_{mrE} - \dot{b}
\]

(16)

Combing (16) and (14) to cancel the term \(\dot{r}_{mr}\), we get the velocity \(V_{mrE}\) and the angular velocity \(\Omega_{mrE}\) of the battery mass \(m_{mr}\) as

\[
V_{mrE} = V - \mathbf{r}_{mr}\Omega + \dot{r}_{mr} - \mathbf{r}_{mr}\Omega_{mr}
\]

\[
\Omega_{mrE} = \Omega_{mr} + \dot{\gamma}
\]

When the mass rotates slowly, we can neglect \(V_{mr}\) and \(\Omega_{mr}\). The translational velocity and the angular velocity can be expressed as

\[
V_{mrE} = V - \dot{r}_{mr}\Omega
\]

\[
\Omega_{mrE} = \dot{\gamma}
\]

(17)

So the kinetic energy of the battery mass is expressed as:

\[
T_{mr} = \frac{1}{2}m_{mr}\|V_{mrE}\|^2 + \frac{1}{2}I_{mrE}^T\Omega_{mrE}\Omega_{mrE}
\]

\[
= \frac{1}{2}V^T\mathbf{M}_{mr}\mathbf{v}
\]

(18)

Then we get the total energy of the SIA glider system as:

\[
T = T_{mr} + T_{rb} + T_b + T_f
\]

\[
= \frac{1}{2}V^T\mathbf{M}\mathbf{v}
\]

(19)

The generalised inertia matrix is

\[
\mathbf{M} = \begin{bmatrix}
\mathbf{M}_c \\
\mathbf{C}_T \\
\mathbf{I}_T
\end{bmatrix}
\]

where \(\mathbf{M}_c = (m_{mr} + m_{rb} + m_b)I_3 + M_{FE}C_t = C_f - m_{rb}\dot{r}_{rb} - m_{mr}\dot{r}_{mr} - m_{mr}\dot{r}_{rb}, \) \(\mathbf{C}_T = I_T = I_b + I_0 + I_{mr}(\gamma) + I_{fe} = m_{mr}\dot{r}_{mr} - m_{rb}\dot{r}_{rb} - m_{rb}\dot{r}_{rb}, \) and \(\mathbf{I}_T = (m_{mr}\dot{r}_{mr} + m_{rb}\dot{r}_{rb} - m_{rb}\dot{r}_{rb})\).

And then, based on (5), we map the generalized momentum \([p^T \pi^T]^T\) from the inertial frame to the generalized momentum \(\eta\) in the body frame as

\[
\mathbf{p} = R_{EB}\mathbf{P}
\]

\[
\mathbf{\pi} = R_{EB}(\mathbf{\pi} + \mathbf{\Omega}\mathbf{P}) + R_{EB}\mathbf{V} \times \mathbf{p} + \mathbf{b} \times \dot{\mathbf{p}}
\]

(20)

Differentiating (20) and using the kinematic matrix (1) and (2), we get the relationship among \(\eta, \nu, \dot{\nu},\) and \(\dot{\eta}\) as

\[
\dot{\mathbf{p}} = R_{EB}(\dot{\mathbf{P}} + \dot{\mathbf{\Omega}}\mathbf{P})
\]

\[
\dot{\mathbf{\pi}} = R_{EB}(\dot{\mathbf{\pi}} + \dot{\mathbf{\Omega}}\mathbf{P}) + R_{EB}\mathbf{V} \times \mathbf{p} + \mathbf{b} \times \dot{\mathbf{p}}
\]

(21)

Substituting (21) into (5), we obtain

\[
\dot{\mathbf{p}} = \mathbf{P} \times \mathbf{\Omega} + \dot{\mathbf{m}}g(R_{EB}^T\mathbf{k}) + R_{EB}^T\sum_{j=1}^{N_b} \mathbf{f}_{exti}
\]

\[
\dot{\mathbf{\pi}} = \mathbf{P} \times \Omega + \mathbf{V} \times \mathbf{P} + \mathbf{R}_{EB}^T\sum_{j=1}^{N_f} \mathbf{r}_{extj}
\]

(22)

Then we substitute (22) into (7), and at last we get the total dynamic model as in (26), where \(\mathbf{F} = R_{EB}^T\sum_{i=1}^{2N} \mathbf{f}_{exti}, \) and \(\mathbf{T} = R_{EB}^T\sum_{j=1}^{N_f} \mathbf{r}_{extj}\).
0 = V \omega_3 (m_{t3} \sin \beta \cos \phi \cos \theta - m_{t3} \sin \alpha \cos \beta \sin \phi \cos \theta) \\
+ m_{mr} \omega_3^2 \left( r_{mrx} \cos^2 \theta + R_{mr} \frac{\sin 2\theta}{2} \cos (\phi + \gamma) \right) - mg \sin \theta - D \cos \alpha \cos \beta - SF \cos \alpha \sin \beta + L \sin \alpha \\
0 = V \omega_3 (-m_{t3} \sin \alpha \cos \beta \sin \theta - m_{t1} \cos \alpha \cos \beta \cos \phi \cos \theta) + mg \sin \phi \cos \theta - D \sin \beta + SF \cos \beta \\

- m_{mr} r_{mrz} \cos \phi \cos \theta + \sin \beta M_{DL1} + \cos \beta M_{DL2} + (M_{f3} - M_{f1}) V^2 \cos^2 \beta \sin 2 \alpha \\
= \left( \frac{V^2 (M_{m1} - M_{m2}) R_{mrz} \sin 2 \alpha \cos \beta \sin \gamma + (M_{m1} - M_{m2}) R_{mrz} \sin 2 \beta \cos \alpha \cos \gamma}{2} \right) \\
- \omega_3^2 R_{mrz} \sin 2 \phi \left( \frac{\sin \gamma \cos \phi (I_{rbx} + I_{f1} - I_{rbz} - I_{f3}) + \sin \phi \cos \gamma (I_{rbx} + I_{f1} - I_{rbz} - I_{f2})}{2} \right) \\
+ T_2 (-R_{mrz} \sin \gamma) + T_3 R_{mrz} \cos \gamma \\
r_{mrz} = \frac{V^2 (M_{m1} - M_{m2}) R_{mrz} \sin 2 \alpha \cos \beta \sin \gamma + (M_{m1} - M_{m2}) R_{mrz} \sin 2 \beta \cos \alpha \cos \gamma}{2} \\
+ \frac{\sin \gamma \cos \phi (I_{rbx} + I_{f1} - I_{rbz} - I_{f3}) + \sin \phi \cos \gamma (I_{rbx} + I_{f1} - I_{rbz} - I_{f2})}{2} \\
+ T_2 (-R_{mrz} \sin \gamma) + T_3 R_{mrz} \cos \gamma \\
= \frac{V^2 (M_{m1} - M_{m2}) R_{mrz} \sin 2 \alpha \cos \beta \sin \gamma + (M_{m1} - M_{m2}) R_{mrz} \sin 2 \beta \cos \alpha \cos \gamma}{2} \\
+ \frac{\sin \gamma \cos \phi (I_{rbx} + I_{f1} - I_{rbz} - I_{f3}) + \sin \phi \cos \gamma (I_{rbx} + I_{f1} - I_{rbz} - I_{f2})}{2} \\
+ T_2 (-R_{mrz} \sin \gamma) + T_3 R_{mrz} \cos \gamma \\
= \frac{\omega_3^2 \cos^2 \theta \left( I_{rbx} + I_{f1} - I_{rbz} - I_{f2} \right) \sin 2 \phi \left( \omega_3 \sin 2 \phi - 2 \sin^2 \phi \right) - T_1 + (m_{t3} - m_{t2}) V^2 \sin \alpha \sin 2 \beta}{2} \\
(45)

\begin{align*}
B. \text{Hydrodynamic forces on the glider}
\end{align*}

In this section, the hydrodynamic forces \( F \) and \( T \) are first expressed as functions of the hydrodynamic angles \( \alpha \) and \( \beta \), which is defined by

\[ \alpha = \tan^{-1} \left( \frac{V_y}{V_x} \right), \beta = \sin^{-1} \left( \frac{V_y}{V} \right), V = ||V|| \]

According to [9], the hydrodynamic force \( F_{hy} \) and moment \( M_{DL} \) are simplified as

\[ F_{hy} = \begin{bmatrix}
-D \\
SF \\
-L
\end{bmatrix} \begin{bmatrix}
(K_{D0} + K_{DQ}) V^2 \\
(K_{D3} V^2) \\
(K_{D3} V^2)
\end{bmatrix} \\
M_{DL} = \begin{bmatrix}
(K_{MR} \beta + K_{MP}) V^2 \\
(K_{M1} + K_{M1}) V^2 \\
(K_{M1} + K_{Mr}) V^2
\end{bmatrix} \begin{bmatrix}
V^2 \\
V^2 \\
V^2
\end{bmatrix}
\]

and then \( F \) and \( T \) are expressed as

\[ F = R_{BC} F_{hy}, T = R_{BC} M_{DL} \]

where

\[ R_{BC} = \begin{bmatrix}
\cos \beta & -\cos \beta & -\sin \gamma \\
\sin \beta & \cos \beta & 0 \\
\sin \beta & -\cos \beta & \alpha
\end{bmatrix} \]

The Hydrodynamic coefficients depend on the glider speed, geometry, and the Reynolds number. CFD, Fluent and other software or towing trials can be used to determine the hydrodynamic coefficients. The added mass and inertial terms, which are included in the added inertial matrix \( M_{f2} \), \( I_{f2} \) and the added hydrodynamic coriolis and centripetal matrix \( C_{f2} \), are given based on analytical method of the strip theory. When the coefficients are known, since \( \alpha \) and \( \beta \) are completely determined by \( V \), the hydrodynamic forces and torques can be viewed as functions of \( V \), i.e. \( F(V), T(V) \).

III. GLIDER MOTION IN THREE DIMENSION

The steady state glider motion includes the 3D spiraling motion. Assuming that the position of the battery is fixed at \( r_{mr} \) and with a constant buoyancy mass, which imply that the control \( m_{tb} = 0 \), the glider equilibria equations in three dimension are
\[ 0 = \mathbf{P} \times \Omega + \mathbf{m}_g (\mathbf{R}_{EB}^T \mathbf{k}) + \mathbf{F} \]  \hfill (25)

\[ 0 = \mathbf{P} \times \mathbf{V} + \mathbf{m}_{mr} \mathbf{r}_{mr} \times (\mathbf{R}_{EB}^T \mathbf{k}) + \mathbf{T} \]  \hfill (26)

After expanding the force equation along \( e_1 \) and \( e_2 \) in (25), and moment equation around \( e_1 \) in (26), we get (27), (28) and (29). We consider the case when the buoyancy mass and the rigid body mass produce the combined effect such that the center of buoyancy of the glider can be studied by letting \( r_{rb} = 0 \) and \( r_b = 0 \). Then \( \mathbf{P} \) and \( \mathbf{I} \) are simplified as

\[ \Omega \times (\mathbf{R}_{EB}^T \mathbf{k}) = 0 \]  \hfill (32)

From (32), we know that the underwater glider moves with constant speed along a circular helix which is aligned with the direction of gravity, hence the angular velocity is \( \Omega = \mathbf{R}_{EB}^T \mathbf{k} \omega_3 \). The spiraling motion can be projected into rotational motion around \( \mathbf{k} \) and an ascending motion along \( \mathbf{k} \), we analyze the rotational motion and then ascending motion by projecting the total velocity \( V \) into the turning direction and the vertical direction as

\[ V \cos (\theta - \alpha) = \omega_3 R \]  \hfill (33)

\[ V \sin (\theta - \alpha) = V_{vertical} \]  \hfill (34)

The steady spiraling motion can be determined by ten parameters: \( V, \alpha, \beta \) which describe the velocity of the glider, \( \omega_3, \phi, \theta \) which describe the glider angular velocity, the controllable buoyancy \( m_b \), the battery position \( r_{mrx} \) and \( \gamma \), and the turning radius \( R \). By combining (25), (26) and (33), we obtain seven equations of the 3D spiral motion. Since the equations may not be independent, we need to specify at least three parameter out of ten to solve for the rest of the seven parameters.

We consider the situation where \( V, \alpha, \beta, \) are known, from which we know the expression of \( \mathbf{T}, \mathbf{F}, \) and \( \mathbf{R}_{BC} \), then we solve for the other seven parameters. In order to make (25) and (26) simpler to solve, we take the inner products with respect to \( \Omega \) on both sides of (25), (26) and take the inner products on both sides of (26) with respect to \( \mathbf{r}_{mr} \), then we get

\[ 0 = \mathbf{\hat{m}}_g \Omega \bullet \Omega + \mathbf{F} \bullet \Omega \]  \hfill (35)

\[ 0 = (\mathbf{P} \times \mathbf{V} + \mathbf{T}) \bullet \Omega \]  \hfill (36)

\[ 0 = (\mathbf{I}_t \Omega \times \Omega) \bullet \mathbf{r}_{mr} + (\mathbf{M}_t \mathbf{V} \times \mathbf{V}) \bullet \mathbf{r}_{mr} + \mathbf{T} \bullet \mathbf{r}_{mr} \]  \hfill (37)

From (35), we can solve for the buoyancy mass as

\[ \hat{m}_g = \frac{-\mathbf{F} \bullet (\mathbf{R}_{EB}^T \mathbf{k})}{g} \]  \hfill (38)

Using (36) and (25), we can get the glider rotate velocity \( \omega_3 \) as

\[ \omega_3 = -\frac{\mathbf{F} + \mathbf{m}_g \mathbf{R}_{EB}^T \mathbf{k} \bullet \mathbf{V}}{\mathbf{T} \bullet \mathbf{R}_{EB}^T \mathbf{k}} \]  \hfill (39)

Note that \( \mathbf{T} \) is also a function of \( \omega_3 \). Hence (39) is a nonlinear equation for \( \omega_3 \), which can be solved analytically if \( \theta, \phi, \) are known. Therefore, supposing solutions of \( \theta, \phi \) are found, we can find \( \hat{m}_g \) and \( \omega_3 \) from (38) and (39). After that, we can solve for turning radius from (33) as

\[ R = \frac{V \cos (\theta - \alpha) \omega_3}{\omega_3} \]  \hfill (40)

With the assumption that we know \( V, \alpha, \beta, \) and \( \hat{m}_g \), we can solve for \( \hat{m}_g, \omega_3 \) and \( R \) as functions of \( \theta \) and \( \phi \). This process has reduced the unknown parameters from seven to four. We still need solve for \( \theta, \phi, \gamma, \) and \( r_{mrx} \). When \( \omega_3 \) is small, (27) and (28) can be used to solve for \( \theta \) and \( \phi \). Then (29) and (37) can be used to solve for \( \gamma \) and \( r_{mrx} \). When \( \omega_3 \) is not small, (27), (28), (29), (37), (38), and (39) have to be solved altogether. We define a recursive vector as

\[ \Delta = [\theta, \phi, \gamma, r_{mrx}, R, \hat{m}_g, \omega_3] \]

We next establish the recursive equations to solve \( \Delta \) as

\[ \Delta^k = \mathbf{F} (\Delta^{k-1}) \]  \hfill (41)

From (27), we solve for \( \theta \) as

\[ \theta = \arcsin \frac{f_\theta}{\sqrt{f_{\theta 1}^2 + f_{\theta 2}^2}} - \lambda_\theta \]  \hfill (42)

where

\[ f_{\theta 1} = V \omega_3 (m_{t2} \sin \beta \cos \phi - m_{t3} \sin \alpha \cos \beta \sin \phi) \]

\[ f_{\theta 2} = -\hat{m}_g \]

\[ f_\theta = D \cos \alpha \cos \beta + SF \cos \alpha \sin \beta - L \sin \alpha \]

\[ -m_{mr} \omega_3^2 \left( r_{mrx} \cos^2 \theta + R_{mr} \sin 2\theta \cos (\phi + \gamma) \right) \]

\[ \lambda_\theta = \frac{f_{\theta 1}}{\sqrt{f_{\theta 1}^2 + f_{\theta 2}^2}}, \cos \lambda_\theta = \frac{f_{\theta 2}}{\sqrt{f_{\theta 1}^2 + f_{\theta 2}^2}} \]

Similarly, from (28), we express the roll angle \( \phi \) as

\[ \phi = \arcsin \frac{f_\phi}{\sqrt{f_{\phi 1}^2 + f_{\phi 2}^2}} - \lambda_\phi \]  \hfill (43)

where

\[ f_{\phi 1} = -\hat{m}_g \cos \theta - m_{mr} \omega_3^2 \sin \frac{2\theta}{2} \]

\[ f_{\phi 2} = V \omega_3 m_{t4} \cos \alpha \cos \beta \cos \theta \]

\[ f_\phi = SF \cos \beta - D \sin \beta - V \omega_3 m_{t4} \sin \alpha \cos \beta \sin \theta + m_{mr} \omega_3^2 \left( -R_{mr} \sin 2\theta \cos^2 \theta \cos \gamma - R_{mr} \sin \gamma (\cos^2 \phi \cos^2 \theta + \sin^2 \theta) \right) \]

\[ \lambda_\phi = \frac{f_{\phi 1}}{\sqrt{f_{\phi 1}^2 + f_{\phi 2}^2}}, \cos \lambda_\phi = \frac{f_{\phi 2}}{\sqrt{f_{\phi 1}^2 + f_{\phi 2}^2}} \]
When $\omega^2$ is quite small, the terms that contains $r_{mx}$ and $\gamma$ disappear from (42) and (43). Hence after we replace $\bar{m}$ by (38), the equations (39), (42), and (43) can be solved recursively for $\theta$ and $\phi$.

We next derive the recursive equations for $r_{mx}$ and $\gamma$. From (29), we express the battery angle $\gamma$ as

$$\gamma = \arcsin \frac{f_1}{\sqrt{f_1^2 + f_2^2}} - \lambda_1$$  \hspace{1cm} (44)

Where $\sin \lambda_1 = \frac{f_1}{\sqrt{f_1^2 + f_2^2}}$, $\cos \lambda_1 = \frac{f_2}{\sqrt{f_1^2 + f_2^2}}$, and $f_1$, $f_2$, $f_3$ are defined in (45). From (37), we get the battery translational position $r_{mx}$ as (46). Therefore, we have shown that the solution of the steady spiraling motion can be derived using a recursive algorithm developed from (38), (39), (40), (42), (43), (44), and (46).

IV. SIMULATION

In this section, we give the simulation results demonstrated by a glider simulation program developed by SIA where hydrodynamic effects are considered. We then compare the results with the solutions obtained by the recursive algorithm for the spiraling motion. The rigid body mass and the battery block mass are $m_{rb} = 54.28$ kg and $m_{mr} = 11$ kg, and the volume displacement mass of the SIA glider is $m = 65.28$ kg. The moving range and the rotation range of the battery block mass are $0.05m < r_{mx} < 0.05m$, $-90^\circ < \gamma < 90^\circ$, and the range of buoyancy adjustment is $0.8 < m_b < 0.8$. The simulation result is shown in Fig. 3. The relation between the battery angle and the glider turning radius is shown in Fig. 3(b). When the block mass has a rotation angle $\gamma = 45^\circ$, we get a spiraling motion equilibrium in Fig. 3(a) with $V = 0.50{3}$ m/s, $\alpha = 1.11^\circ$, $\beta = -1.83^2$, $\omega_1 = 0.0064$ rad/s, $\phi = -21.31^\circ$, $\theta = -37.5^\circ$, and the radius of the spiraling motion is $R \approx 61.83$. With the assumption that $V, \alpha, \beta$ are known, we initiate the recursive algorithm from the vertical gliding motion parameters $m_b = 0.001$ kg, $r_{mx} = 0.001$ m, $\gamma = 0.001^\circ$, $\omega_1 = 0.001$ rad/s, $\phi = -0.001^\circ$, $\theta = -0.001^\circ$. Then the algorithm converges to the solutions as $m_b = 0.036$, $r_{mx} = 0.011m$, $\gamma = 39.42^\circ$, $\omega_1 = 0.0067$ rad/s, $\phi = -21.22^\circ$, $\theta = -37.59^\circ$, $R = 58.66m$. The errors between the recursive solutions and the simulation results are less than 5% for each parameter.

V. CONCLUSIONS AND FUTURE WORKS

We analyze the steady state spiraling motion of the SIA glider by solving for the parameters that completely characterize the spiraling motion. A recursive algorithm is devised after the motion equations are significantly simplified to find the exact solutions. Future works include analysis of the convergence conditions for the recursive algorithm, and comparisons between experimental and analytical results.
